Observational astronomy is a division of astronomy that is concerned with recording data about the observable universe, in contrast with theoretical astronomy, which is mainly concerned with calculating the measurable implications of physical models. It is the practice and study of observing celestial objects with the use of telescopes and other astronomical instruments. As a science, the study of astronomy is somewhat hindered in that direct experiments with the properties of the distant univer

Historically, astronomical observatories consisted generally in a building or group of buildings where observations of astronomical objects such as sunspots, planets, asteroids, comets, stars, nebulae, and galaxies in the visible wavelengths of the electromagnetic spectrum were conducted. At first, for millennia, astronomical observations have been made with naked eyes.

The instance when the Sun is exactly above the Equator and day and night are of equal length is called: Optical observatories have a long history. The predecessors of astronomical observatories were monolithic structures that tracked the positions of the Sun, Moon, and other celestial bodies for timekeeping or calendrical purposes.

Moving on from radio astronomy, Chris Haniff (Cavendish Laboratory, Cambridge) discussed the pros and cons of the Moon as a platform for optical interferometers. Interferometry is a powerful technique for resolving small angular scales, and has many important astrophysical applications, including the study of extrasolar planetary systems.
