This paper is devoted to a numerical method for the approximation of a class of free boundary problems of Bernoulli's type, reformulated as optimal shape design problems with appropriate shape functionals.

notice that shape optimization is a well established tool to solve free boundary value problems like (1.1), see e.g. [3, 4, 5, 7, 9, 10, 11, 12, 13, 14]. 2 Sufficient optimality conditions In [4, 5, 7, 9] we computed the boundary integral representation of the shape gradient

Abstract: We consider shape optimization problems for general integral functionals of the calculus of variations that may contain a boundary term. In particular, this class includes optimization problems governed by elliptic equations with a Robin condition on the free boundary.

Definition. Mathematically, shape optimization can be posed as the problem of finding a bounded set, minimizing a functional $J(\Omega)$, possibly subject to a constraint of the form $\chi(\Omega) \leq c$. Usually we are interested in sets which are Lipschitz or C^1 boundary and consist of finitely many components, which is a way of saying that we would like to find a rather pleasing shape as a solution, not some jumble of ...

The essential idea of free-shape optimization, and where it differs from other shape optimization techniques, is that the allowable movement of the outer boundary is automatically determined, thus relieving users of the burden of defining shape perturbations. The optimization problem for this tutorial is stated as:
